- Security with Aspect Oriented Programming:
 - Application-Specific Security (Task 1.4)
- Metadata Driven Development Process
- Case Study: A Defense PLM Application

- Problem:
 - Extend applications to satisfy new requirements
 - Extension cannot be modularized but affects functionality crosscutting the application
 - Increased implementation effort
- Solution:
 - AOSD decreases development effort by specifying extensions systematically in a single class (*aspect*) and then automatically modifying the involved method calls throughout the application
 - Extensions can be specified before, after or around the method call
 - Modifications can be introduced at compile-, load- or run-time
- AOSD is a means to systematically address evolving security requirements & to align with separation-of-concerns principle

- Point: position within code
- Pointcuts: specific, selected points in application code
 - Execution: picks out points defining method execution (callee side)
 - Call: points defining method execution (caller side)
 - Set: picks out points defining field modification
 - Get: picks out points defining field access
 - Cflow: picks out points defining a control flow
 - Handler: picks out points defining where an exception is caught in a catch clause
- Composed Pointcut: using logical operators
- Advices: define what to do at the pointcuts
 - Around: invoked *around* the point (original code replaced)
 - Before: invoked *before* the point is reached
 - After: invoked *after* the point has been reached

Example of a pointcut

Cflow composition expresses the idea of the stack trace
(with a finer level of selection up to parameters types)

```
@Execution * Data.get*(..) IN * Display.addTable(Data)
```

In the control flow of Display.addTable()

```
public class Display {  
    public void addTable(Data some_data) {  
        int id = some_data.getId();  
        ...  
    }  
}
```

Invocation of Data.getId()

```
aDisplay.addTable(some_data);
```

Will match this call

```
some_data.getId();
```

But not this call

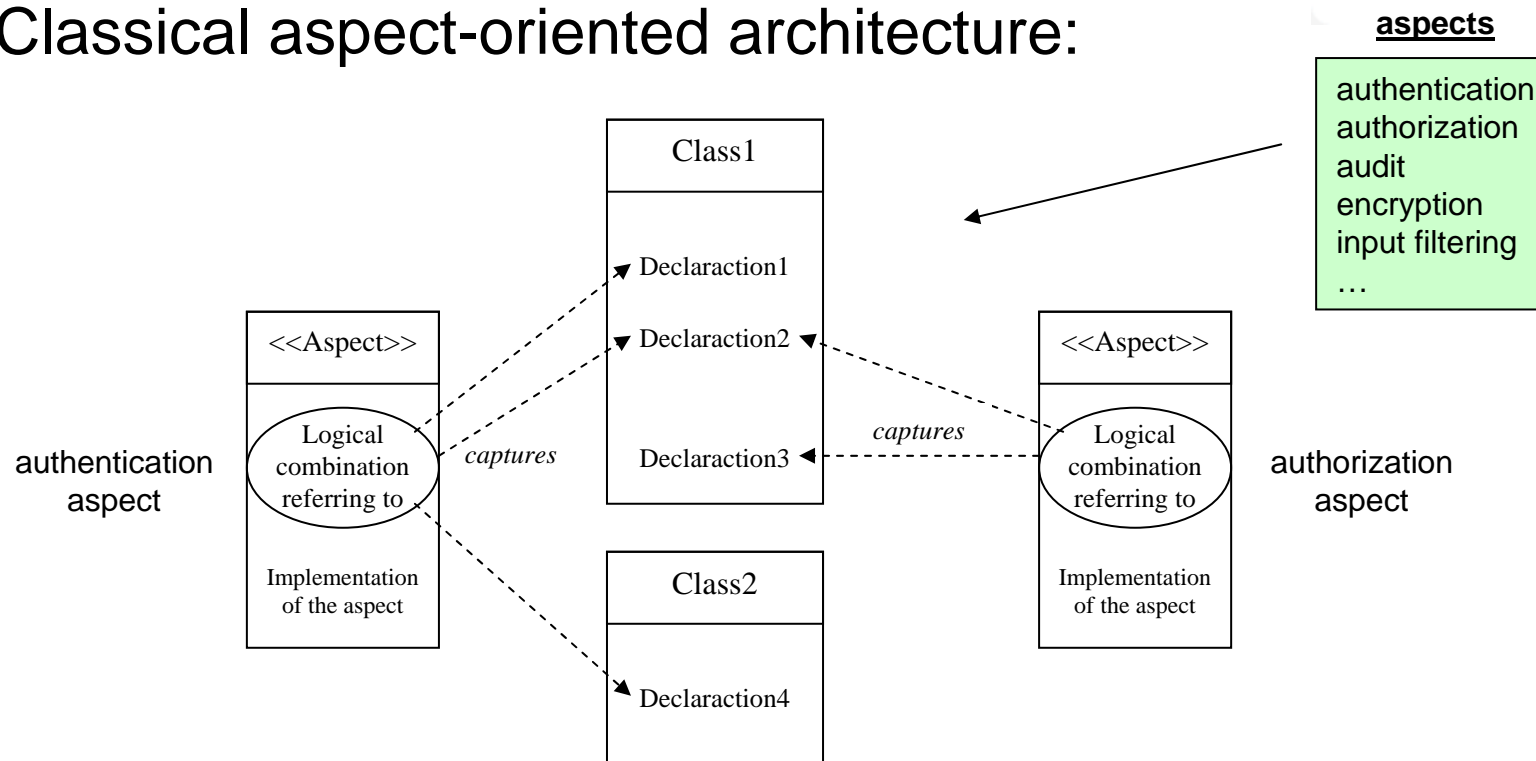

- AOSD is available for use in Java environments and .NET compliant languages
- AspectJ plug-in for Eclipse/NetWeaver development platform
- Performance impact
 - Compile-, and load-time:
 - The overhead of five *around* advices applied to a *method call* point
 - AspectJ 1.1.1 **0.000097** ms/call
 - (Source: BEA Systems)
 - Run-time:
 - The overhead of five *around* advices applied to a *method call* point
 - AspectWerkz 0.10 RC1 **0.000163** ms/call
 - JBoss AOP 1.0Beta **0.000263** ms/call
 - (Source: BEA Systems)

Metadata Driven Development Process

- Why use Metadata ?
- Classical aspect-oriented architecture:

- Can we improve the direct relationship between the pointcuts declarations and the core code ?

- Metadata

- Since Version 1.5 (“Tiger”), Java supports annotations. It also provides a reflection API.

```
/* Associates an author notice with the annotated API element.  
*/ public @interface Author { String value(); }
```

```
@Author("Maarten Rits")  
public class SomeClass { ... }
```

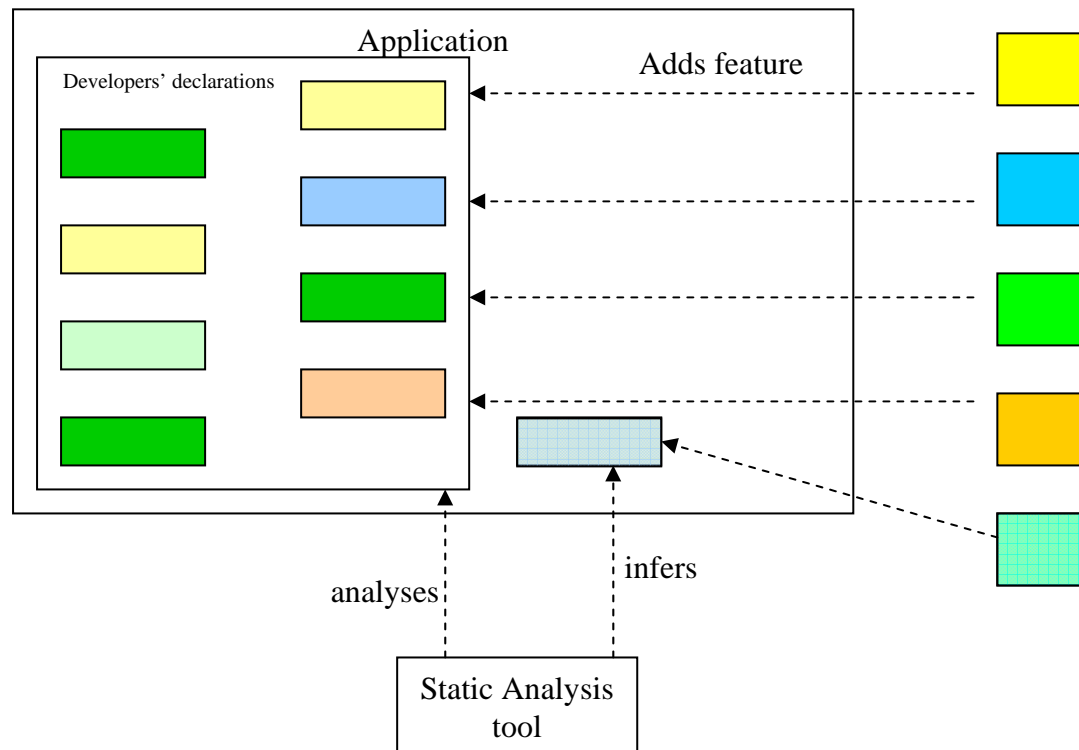

- AspectJ allows the weaving of metadata into bytecode:

- Declare @method: * *.someMethod(..) : @Audit/@Authentication/ etc.

- JML annotations ...

“you won’t be able to use the annotations/metadata syntax in Java 1.5 to write JML specifications. It’s simply not powerful enough for that.”

- We would like to express security properties like “authentication needs to occur before authorization” etc.

Primary Annotations are Java annotations manually written within the code of an application, or explicitly woven by a non-conditional aspect.

Secondary Annotations are Java annotations woven by an external program, based on primary or secondary annotations.

1. Write the core of the application
2. Insert primary annotations
3. Infer secondary annotations
4. Write and weave the code for the concerns
5. **Proof the adherence to high level security properties***

*Related work: [M. Pavlova](#), [G. Barthe](#), [L. Burdy](#), [M. Huisman](#), and [J.-L. Lanet](#). Enforcing high-level security properties for applets. In P. Paradinis and J.-J. Quisquater, *Proceedings of CARDIS'04*, Toulouse, France, August 2004. Kluwer Academic Publishers.

- Focuses on smart card applications
 - proposes a method to translate high level security properties into JML annotations (propagation of annotations)
 - Whether the applet respects its annotations can be established with the existing tools for JML (JACK, ESC/Java, Loop, etc.)
- Example of JML annotation
 - “No nested transactions”
 - A static ghost variable TRANS is declared that keeps track of whether there is a transaction in progress.

```
/*@ static ghost int TRANS == 0; @*/
```

The method beginTransaction is annotated as follows.

```
/*@ requires TRANS == 0;  
@ assignable TRANS;  
@ ensures TRANS == 1; @*/  
public static native void beginTransaction()  
throws TransactionException;
```

- Case Study: A Defense PLM Application

- Specific requirements for screen marking and access control (based on CAVEAT and clearance level) cf. DEIG DSSRS
- SAP Research analyses Enterprise Portal Solution
 - Java-based iViews
 - Aspect Oriented Software Development (AOSD)
- Demonstrator for Enterprise Portal 5.0:
 - Implementation of screen marking and access control in Java
 - Selected iViews are:
 - NotificationsPerObject
 - CreateNotifications
 - FunctionalLocationSelection
- Demonstrator with AOSD in NetWeaver Studio:
 - Reproducing a Web Dynpro structure (aka MVC)
 - Featuring aspects for:
 - Screen marking
 - XACML for a fully declarative and context-based access control
 - Performance overhead compared to hand-coded solution: **20-25 ms** (total application execution time in test = 2000 ms)

PLM in Enterprise Portal 5.0
